

Training in ade4 in R - Module I: Basic methods

Principal component analysis

Stéphane Dray

2021-04-19

Data structure

- One table with p variables measured on n individuals
- All variables are **quantitative**
- For instance
 - sites \times environmental variables
 - species \times traits
 - individuals \times alleles
 - populations \times alleles

Objectives

- Identify what is the main information contained in the table
 - Identify which variables are the most linked
 - Identify the principal differences/similarities between individuals

Data

We consider the **meaudret** data set

```
library(ade4)
data(meaudret)
names(meaudret)
```

```
## [1] "env"      "design"    "spe"      "spe.names"
```

```
dim(meaudret$env)
```

```
## [1] 20  9
```

```
names(meaudret$env)
```

```
## [1] "Temp" "Flow" "pH"    "Cond" "Bdo5" "Oxyd" "Ammo" "Nitr" "Phos"
```

The data set contains an environmental table with 20 measurements of 9 environmental variables. The measurements have been made in 6 sites at each season along a small French stream (see `?meaudret`)

```
head(meaudret$design)
```

```
##      season site
## sp_1 spring  S1
## sp_2 spring  S2
## sp_3 spring  S3
## sp_4 spring  S4
## sp_5 spring  S5
## su_1 summer  S1
```

We want to know

- what are the main environmental gradients, i.e., which variables co-vary (if any)
- which samples have similar/different environmental conditions

Principal component analysis

- \mathbf{X} contains centred or scaled variables
- $\mathbf{Q} = \mathbf{I}_p$ is the identity matrix (diagonal matrix with 1s)
- $\mathbf{D} = \frac{1}{n}\mathbf{I}_n$ is the diagonal matrix with $\frac{1}{n}$

Maximized criteria

- For individuals

$$Q(\mathbf{a}) = \|\mathbf{XQa}\|_{\mathbf{D}}^2 = \|\mathbf{Xa}\|_{\frac{1}{n}\mathbf{I}_n}^2 = \text{var}(\mathbf{Xa}) = \lambda$$

- For variables

- Centred data ($x_{ij} - \bar{x}_j$)

$$S(\mathbf{b}) = \|\mathbf{X}^\top \mathbf{D} \mathbf{b}\|_{\mathbf{Q}}^2 = \left\| \frac{1}{n} \mathbf{X}^\top \mathbf{b} \right\|_{\mathbf{I}_p}^2 = \sum_{j=1}^p \text{cov}^2(\mathbf{x}_j, \mathbf{b}) = \lambda$$

- Scaled data ($(x_{ij} - \bar{x}_j)/s_j$)

$$S(\mathbf{b}) = \|\mathbf{X}^\top \mathbf{D} \mathbf{b}\|_{\mathbf{Q}}^2 = \left\| \frac{1}{n} \mathbf{X}^\top \mathbf{b} \right\|_{\mathbf{I}_p}^2 = \sum_{j=1}^p \text{cor}^2(\mathbf{x}_j, \mathbf{b}) = \lambda$$

The `dudi.pca` function

Arguments

```
args(dudi.pca)
```

```
## function (df, row.w = rep(1, nrow(df))/nrow(df), col.w = rep(1,  
##      ncol(df)), center = TRUE, scale = TRUE, scannf = TRUE, nf = 2)  
## NULL
```

- `df` is a `data.frame` with the data
- `row.w` and `col.w` are optional vectors of weights
- `center` and `scale` define the standardization of the data
- `scannf` and `nf` allow to set the number of dimensions to interpret

```
pca.meau <- dudi.pca(meaudret$env, scannf = FALSE)
```

Returned values

```
names(pca.meau)
```

```
## [1] "tab" "cw" "lw" "eig" "rank" "nf" "c1" "li" "co" "l1"  
## [11] "call" "cent" "norm"
```

It returns an object of class **dudi** containing:

- **\$eig**: eigenvalues ($\mathbf{\Lambda}$)
- **\$cw**: column weights ($\mathbf{Q} = \mathbf{I}_p$)
- **\$lw**: row weights ($\mathbf{D} = \frac{1}{n} \mathbf{I}_n$)
- **\$tab**: transformed data table (\mathbf{X})
- **\$c1**: principal axes or variable loadings (\mathbf{A})
- **\$li**: row scores ($\mathbf{L} = \mathbf{XA}$)
- **\$l1**: principal components (\mathbf{B})
- **\$co**: column scores ($\mathbf{C} = \frac{1}{n} \mathbf{X}^\top \mathbf{B}$)

Graphical representation and interpretation

As we have *two* analyses (individuals and variables spaces), two representations can be defined:

- **distance biplot** where \mathbf{A} and $\mathbf{L} = \mathbf{X}\mathbf{A}$ ($\$c1$, $\$li$) are superimposed.
- **correlation biplot** where \mathbf{B} and $\mathbf{C} = \frac{1}{n}\mathbf{X}^\top\mathbf{B}$ ($\$l1$, $\$co$) are superimposed.

In the first interpretation, PCA finds coefficients for variables ($\$c1$) to compute a linear combination ($\$li$) that provides an ordination of individuals with the greatest dispersion (maximum variance).

In the second interpretation, PCA provides a linear combination ($\$l1$) that maximise the correlations ($\$co$) with all variables (or covariances for centred PCA). Hence, it is the best summary of the variables.

The biplot function

```
library(adegraphics)
```

```
biplot(pca.meau)
```

```
biplot(pca.meau, permute = TRUE)
```

Separate representations

```
s.label(pca.meau$li)
```

```
s.arrow(pca.meau$co)
```

Separate representations

```
s.label(pca.meau$li)
```

```
s.corcircle(pca.meau$co)
```

Separate representations

```
s.class(pca.meau$li, meaudret$des
```

```
s.arrow(pca.meau$co)
```

To scale or not to scale

Scaling should be performed when we do not want that differences in variances affect the results

```
pca.meau.c <- dudi.pca(meaudret$env, scannf = FALSE,  
  scale = FALSE)
```

In our case, we must scale the data as differences in variances are mainly due to differences in units

Inertia statistics

```
summary(pca.meau)
```

```
## Class: pca dudi
## Call: dudi.pca(df = meaudret$env, scannf = FALSE)
##
## Total inertia: 9
##
## Eigenvalues:
##      Ax1      Ax2      Ax3      Ax4      Ax5
##  5.1747  1.3204  1.0934  0.7321  0.4902
##
## Projected inertia (%):
##      Ax1      Ax2      Ax3      Ax4      Ax5
##  57.497  14.671  12.149   8.135   5.447
##
## Cumulative projected inertia (%):
##      Ax1  Ax1:2  Ax1:3  Ax1:4  Ax1:5
##  57.50  72.17  84.32  92.45  97.90
##
## (Only 5 dimensions (out of 9) are shown)
```

PCA in practice
